1 Introduction

Proofs generated by SAT-solvers can be huge. Checking their correctness can not only take a long time but also consume a lot of memory. In an ongoing project for controller synthesis based on the extraction of interpolants from SMT-proofs [14], for example, post-processing a proof takes hours and may reach the limit of memory available today in a single node of a computer cluster (256GB). This issue is even more relevant in application scenarios in which the proof consumer, who is interested in independently checking the correctness of the proof, might have less available memory than the proof producer. This is in part because, while the proof checker reads a usual proof file and checks the proof it contains, every proof node (containing a clause) that is loaded into memory has to be kept there until the end of the whole proof checking process, since the proof checker does not know whether a proof node will still need to be used and re-reading the proof file to reload and recheck proof nodes would be too time-consuming.

To address this issue, recently proposed proof formats such as DRUP [12] and BDRUP [13] allow enriching a proof file with instructions that inform a proof checker when a proof node can be released from memory. Other proof formats, such as the TraceCheck format [3] could also be enriched analogously. Such node deletion instructions can be added by a proof-generating SAT-solver during proof search in the periodic clean-up of its database of derived learned clauses; for every clause the SAT-solver deletes during this phase, this deletion can be recorded in the proof file.

This paper explores the possibility of post-processing a proof in order to increase the amount of deletion instructions in the proof file. The more deletion instructions, the less memory the proof checker will need. Therefore, this *deletion-during-proof-postprocessing* approach ought to be seen not as a replacement but rather as an independent complement to the *deletion-during-proof-search* already performed by state-of-the-art proof-generating SAT-solvers.

The new methods proposed here exploit an analogy between proof checking and playing *Pebbling Games* [15, 10]. The particular version of pebbling game

relevant for proof checking is defined precisely in Section 3 and the analogy to proof checking is explained in detail in Section 4. The proposed pebbling algorithms are greedy (Section 6) and based on heuristics (Section 7). As discussed in Sections 4 and 5, approaches based on exhaustive enumeration or on encoding as a SAT problem would not fare well in practice.

The proof space compression algorithms described here are not restricted to proofs generated by SAT-solvers. They are general DAG pebbling algorithms, that could be applied to proofs represented in any calculus where proofs are directed acyclic graphs (including the special case of tree-like proofs). It is, nevertheless, in SAT and SMT that proofs tend to be largest and in most need of space compression. The underlying propositional resolution calculus (described in Section 2) satisfies the DAG requirement. The experiments (Section 8) evaluate the proposed algorithms on thousands of SAT- and SMT-proofs.

2 Propositional Resolution Calculus

A *literal* is a propositional variable or the negation of a propositional variable. The *complement* of a literal ℓ is denoted $\bar{\ell}$ (i.e. for any propositional variable p , $\bar{p} = \neg p$ and $\overline{\neg p} = p$). The set of all literals is denoted by \mathcal{L} . A *clause* is a set of literals. \perp denotes the *empty clause*.

Definition 1 (Proof). A proof φ is a tuple $\langle V, E, v, \Gamma \rangle$, such that $\langle V, E \rangle$ is a labeled directed acyclic graph whose edges are labeled with literals $\ell \in \mathcal{L}$, i.e. $E \subseteq V \times \mathcal{L} \times V$, $v \in V$, Γ is a clause and one of the following holds:

1. $V = \{v\}, E = \emptyset$
2. There are proofs $\varphi_L = \langle V_L, E_L, v_L, \Gamma_L \rangle$ and $\varphi_R = \langle V_R, E_R, v_R, \Gamma_R \rangle$ such that there exists a literal $\ell, \bar{\ell} \in \Gamma_L$ and $\ell \in \Gamma_R$, then

$$\begin{aligned} &v \text{ is a new node} \\ &V = V_L \cup V_R \cup \{v\} \\ &E = E_L \cup E_R \cup \left\{ v_L \xrightarrow{\bar{\ell}} v, v_R \xrightarrow{\ell} v \right\} \\ &\Gamma = (\Gamma_L \setminus \{\bar{\ell}\}) \cup (\Gamma_R \setminus \{\ell\}) \end{aligned}$$

v is called the root of φ and Γ its conclusion. φ_L and φ_R are premises of φ and φ is a child of both φ_L and φ_R . Γ is called the resolvent of Γ_L and Γ_R with pivot ℓ . A proof ψ is a subproof of a proof φ , if there is a path from φ to ψ in the transitive closure of the premise relation. A subproof ψ of φ which has no premises is an axiom of φ . V_φ and A_φ denote, respectively, the set of nodes and axioms of φ . P_v^φ denotes the premises and C_v^φ the children of the subproof with root v in a proof φ . When a proof is represented graphically, the root is drawn at the bottom and the axioms at the top. The length of a proof φ is the number of nodes in V_φ and is denoted by $l(\varphi)$. \square

Note that in case 2 of Definition 1 V_L and V_R are not required to be disjoint. Therefore the underlying structure of proofs are DAGs as opposed to simple trees. Modern SAT- and SMT-solvers, using techniques of conflict driven clause learning, produce proofs of such kind [5, 4]. The reuse of proof nodes plays a central role in proof compression [9]. Also note that a DAG corresponding to a proof by definition has exactly one sink, also called its root node. For example a node of a proof $\langle V, E, v, I \rangle$ will be meant to be some $s \in V$. From hereon, if free from ambiguity, proofs and their underlying DAGs will not be distinguished.

3 Pebbling Game

Pebbling games are played on graphs and pebbles are placed on nodes following the rules of the game. The goal is to put a pebble on some target node. Pebbling games were introduced in the 1970's to model programming language expressiveness [18, 21] and compiler construction [20]. More recently, pebbling games have been used to investigate various questions in parallel complexity [6] and proof complexity [2, 8, 16]. They are used to obtain bounds for space and time requirements and trade-offs between the two measures [7, 1]. From hereon *to pebble* means to mark a node with a pebble and *to unpebble* means to remove the mark of a node.

Definition 2 (Bounded Pebbling Game). *The Bounded Pebbling Game is played by one player on a DAG $G = (V, E)$ with one distinguished node $s \in V$. The goal of the game is to pebble s , respecting the following rules:*

1. *A node v is pebbleable iff all predecessors of v in G are pebbled and v is currently not pebbled.*
2. *Pebbled nodes can be unpebbled at any time.*
3. *Once a node has been unpebbled, it can not be pebbled again later.*

The game is played in rounds. Every round the player chooses a node $v \in V$, such that v is pebbled or pebbleable. The move of the player in this round is $p(v)$, if v is pebbleable and $u(v)$ if v is pebbled, where $p(\cdot)$ and $u(\cdot)$ correspond to pebbling and unpebbling a node respectively. \square

Not that due to rule 1 the move in each round is uniquely defined by the chosen node v . The distinction of the two kinds of moves is just made for presentation purposes. Also note that as a consequence of rule 1, pebbles can be put on nodes without predecessors at any time. Playing the game on a proof φ means to play the game on the underlying DAG with the distinguished node being the root of φ .

In this work we investigate space requirements when time requirements are fixed. Fixing time is a design choice, see Section 4, and it corresponds to rule 3. Including this rules sets a bound $O(|V|)$ for the number of rounds.

Definition 3 (Strategy). A pebbling strategy σ for the Bounded Pebbling Game, played on a DAG $G = (V, E)$ and distinguished node s , is a sequence of moves $(\sigma_1, \dots, \sigma_n)$ of the player such that $\sigma_n = p(s)$.

The following definition allows to measure how many pebbles are required to play the Bounded Pebbling Game on a given graph.

Definition 4 (Pebbling number). The pebbling number of a pebbling strategy $(\sigma_1, \dots, \sigma_n)$ is defined as $\max_{i \in \{1 \dots n\}} |\{v \in V \mid v \text{ is pebbled in round } i\}|$. The pebbling number of a DAG G and node s is defined as the minimum pebbling number of all pebbling strategies for G and s .

Note that the definitions 2 and 3 leave freedom when to do unpebbling moves. With the aim of finding strategies with low pebbling numbers, there is a canonical way when to do these moves, as will be shown later.

The Bounded Pebbling Game from definition 2 differs from the Black Pebbling Game discussed in [11, 19] in two aspects. Firstly, the Black Pebbling Game does not include rule 3. Excluding this rule allows for pebbling strategies with lower pebbling numbers ([20] has an example on page 1), which can have the cost of exponentially more moves [7]. Secondly, when pebbling a node in the Black Pebbling Game, one of its predecessors' pebbles can be used instead of a fresh pebble (i.e. a pebble can be moved). The trade-off when allowing to moving pebbles are discussed in [7]. Deciding whether the pebbling number of a graph G and node s is smaller than k is PSPACE-complete in the absence of rule 3 [10] and NP-complete when rule 3 is included [20].

4 Pebbling and Proof Processing

The problem of processing a proof with minimal memory consumption is analogous to the problem of finding a pebbling strategy with minimal pebbling number. Proof processing could be checking its correctness, manipulating it or extracting information from it. The following definition makes the notion of proof processing formal.

Definition 5 (Proof Processing).

Let φ be a proof with nodes V and T be an arbitrary set. We call a function $f : V \times T \times T \rightarrow T$ a processing function if there is a function $g_f : V \rightarrow T$ such that for every $v \in V$ with $P_v^\varphi = \emptyset$ (i.e. v represents an axiom), $g_f(v) = f(v, t_1, t_2)$ for all $\{t_1, t_2\} \subseteq T$. The apply function $\text{ap} : V \times T^{V \times T \times T} \rightarrow T$ is defined recursively as follows.

$$\text{ap}(v, f) = \begin{cases} f(v, \text{ap}(pr_1, f), \text{ap}(pr_2, f)) & \text{if } v \text{ has premises } pr_1 \text{ and } pr_2 \\ g_f(v) & \text{otherwise} \end{cases}$$

Processing a node v with some processing function f means computing the value $\text{ap}(v, f)$. Processing a proof means to process its root node. \square

Example 1. Checking the correctness of a proof (i.e. checking for the absence of faulty resolution steps) can be checked in terms of the following processing function with $T = \{\top, \perp\}$ and \wedge being the usual boolean and-operation.

$$f(v, w_1, w_2) = \begin{cases} \top & \text{if } v \text{ has no premises} \\ w_1 \wedge w_2 & \text{if the conclusion of } v \text{ is a resolvent} \\ & \text{of the conclusions of its premises} \\ \perp & \text{otherwise} \end{cases}$$

Processing a proof with this processing function yields \top iff the proof is a correct resolution proof. \square

In Section 3 it was pointed out that strategies with minimal pebbling numbers may require to play exponentially many rounds. Every round of the game corresponds to an I/O operation and, if the action of the player is to pebble a node, the processing of the node. The goal of proof compression is to reduce the hardness of proof processing, therefore requiring exponentially many I/O operations and processing steps is not a viable option. That is the reason why we chose the Bounded Pebbling Game for our purpose. In the Bounded Pebbling Game the number of rounds is essentially the number of nodes.

In order to process a node, the results of processing its premises are used and therefore have to be stored in memory. The requirement of having premises in memory corresponds to rule 1 of the Bounded Pebbling Game. Processing a node and I/O operations are typically more expensive than extra memory consumption, therefore in our setting every node can be processed only once, which corresponds to rule 3. A node that has been processed can be removed from memory, which corresponds to rule 2. Note that removing a node and its results too early in combination with 3 makes it impossible to process the whole proof. The best moment for removing a node from memory is canonical, as shown later in this chapter.

Definition 5 leaves freedom in what order to process nodes. The order in which nodes are processed is essential for the memory consumption, just like the order of pebbling nodes in the pebbling game is essential for the pebbling number. The following definition allows us to relate pebbling strategies with orderings of nodes.

Definition 6 (Topological Order). *A topological order of a proof φ is a total order relation \prec on V_φ , such that for all $v \in V_\varphi$, for all $p \in P_v^\varphi : p \prec v$. A pebbling strategy $\sigma = (\sigma_1, \dots, \sigma_n)$ respects a topological order \prec if $j < i$ iff $\sigma_j \prec \sigma_i$. \square*

A topological order \prec of a proof φ can be represented as a sequence (v_1, \dots, v_n) of proof nodes, by defining $\prec := \{(v_i, v_j) \mid 1 \leq i < j \leq n\}$. This sequence can be interpreted as a particular pebbling strategy for the game played on φ . The requirement of topological orders to order premises higher than their children corresponds to rule 1 of the Bounded Pebbling Game. The antisymmetry together with the fact that $V = \{v_1, \dots, v_n\}$ corresponds to rule 3. The only thing

missing are the unpebbling moves. The following theorem states that unpebbling moves are given implicit, when the goal is to find strategies with small pebbling numbers.

Definition 7 (Canonical Topological Pebbling Strategy). *The canonical topological pebbling strategy σ for a proof φ , its root node s and a topological order \prec represented as a sequence (v_1, \dots, v_n) is defined recursively:*

$$\sigma_1 = p(v_1)$$

$$\sigma_i = \begin{cases} u(v_j) & \text{if there exists } j \text{ such that for all } v \in C_{v_j}^\varphi : \\ & \text{there exists } k < i, \sigma_k = p(v) \text{ and} \\ & \text{for all } l : k < l < i, \sigma_l \neq u(v_j) \\ p(v_j) & \text{otherwise where } j = \min(k \mid \text{for all } l < i : \sigma_l \neq p(v_k)) \end{cases}$$

□

The following theorem shows that unpebbling moves can be omitted from strategies for the Bounded Pebbling Game, when the goal is to produce strategies with low pebbling numbers.

Theorem 1. *The canonical pebbling strategy has the minimum pebbling number among all pebbling strategies that respect the topological order \prec .*

Proof. (Sketch) All the pebbling strategies respecting \prec differ only w.r.t. their unpebbling moves. Consider the unpebbling of an arbitrary node v in the canonical pebbling strategy. Unpebbling it later could only possibly increase the pebble number. To reduce the pebble number, v would have to be unpebbled earlier than some preceding pebbling move. But, by definition of canonical pebbling strategy, the immediately preceding pebbling move pebbles the last child of v w.r.t. \prec . Therefore, unpebbling v earlier would make it impossible for its last child to be pebbled later without violating the rules of the game. □

As a consequence of Theorem 1 is that finding pebbling strategies with low pebbling numbers can be reduced to constructing topological orders. The memory required to process a proof using some topological order can be measured by the pebbling number of the pebbling strategy corresponding to the order.

Definition 8 (Space). *The space $s(\varphi, \prec)$ of a proof φ and a topological order \prec is the pebbling number of the canonical topological pebbling strategy of φ , its root and \prec .* □

The problem of compressing the space of a proof φ and a topological order \prec is the problem of finding another topological order \prec' such that $s(\varphi, \prec') < s(\varphi, \prec)$. The following theorem shows that the number of possible topological orders is very large; hence, enumeration is not a feasible option when trying to find a good topological order.

Theorem 2. *There is a sequence of proofs $(\varphi_1, \dots, \varphi_m, \dots)$ such that $l(\varphi_m) \in O(m)$ and $|T(\varphi_m)| \in \Omega(m!)$, where $T(\varphi_m)$ is the set of possible topological orders for φ_m .*

Proof. Let φ_m be a perfect binary tree with m axioms. Clearly, $l(\varphi_m) = 2m - 1$. Let (v_1, \dots, v_n) be a topological order for φ_m . Let $A_\varphi = \{v_{k_1}, \dots, v_{k_m}\}$, then $(v_{k_1}, \dots, v_{k_m}, v_{l_1}, \dots, v_{l_{n-m}})$, where $(l_1, \dots, l_{n-m}) = (1, \dots, n) \setminus (k_1, \dots, k_m)$, is a topological order as well. Likewise, $(v_{\pi(k_1)}, \dots, v_{\pi(k_m)}, v_{l_1}, \dots, v_{l_{n-m}})$ is a topological order, for every permutation π of $\{k_1, \dots, k_m\}$. There are $m!$ such permutations, so the overall number of topological orders is at least factorial in m (and also in n).

5 Pebbling as a Satisfiability Problem

To find the pebble number of a proof, the question whether the proof can be pebbled using no more than k pebbles can be encoded as a propositional satisfiability problem. In this chapter let φ be a proof with nodes v_1, \dots, v_n and let v_n be its the root node. Due to rule 3 of the Bounded Pebbling Game, the number of moves that pebble nodes is exactly n and due to theorem 1 determining the order of these moves is enough to define a strategy. For every $x \in \{1, \dots, k\}$, every $j \in \{1, \dots, n\}$ and every $t \in \{0, \dots, n\}$ there is a propositional variable $p_{x,j,t}$. The variable $p_{x,j,t}$ being mapped to \top by a valuation is interpreted as the fact that in the t 'th round of the game node v_j is marked with pebble x . Round 0 is interpreted as the initial setting of the game before any move has been done.

Definition 9 (Pebbling SAT encoding). *The following constraints, combined conjunctively, are satisfiable iff there is a pebbling strategy σ for φ with pebbling number smaller or equal k . In case the formula is satisfiable, a pebbling strategy can be read off from any satisfying assignment.*

1. *The root is pebbled in the last round*

$$\Psi_1 = \bigvee_{x=1}^k p_{x,n,n}$$

2. *No node is pebbled initially*

$$\Psi_2 = \bigwedge_{x=1}^k \bigwedge_{j=1}^n (\neg p_{x,j,0})$$

3. *A pebble can only be on one node in one round*

$$\Psi_3 = \bigwedge_{x=1}^k \bigwedge_{j=1}^n \bigwedge_{t=1}^n \left(p_{x,j,t} \rightarrow \bigwedge_{i=1, i \neq j}^n \neg p_{x,i,t} \right)$$

4. For pebbling a node, its premises have to be pebbled the round before and only one node is being pebbled each round.

$$\Psi_4 = \bigwedge_{x=1}^k \bigwedge_{j=1}^n \bigwedge_{t=1}^n \left((\neg p_{x,j,t} \wedge p_{x,j,(t+1)}) \rightarrow \left(\bigwedge_{i \in P_j^\varphi} \bigvee_{y=1, y \neq x}^k p_{y,i,t} \right) \wedge \left(\bigwedge_{i=1}^n \bigwedge_{y=1, y \neq x}^k \neg (\neg p_{y,i,t} \wedge p_{y,i,(t+1)}) \right) \right)$$

The sets A_φ and P_j^φ are interpreted as sets of indices of the respective nodes.

This encoding is polynomial, both in n and k . However constraint 4 accounts to $O(n^3 * k^2)$ clauses. Even small resolution proofs have more than 1000 nodes and pebble numbers bigger than 100, which adds up to 10^{13} clauses for constraint 4 alone. Therefore, although theoretically possible to play the pebbling game via SAT-solving, this is practically infeasible for compressing proof space. The following theorem proves the correctness of the encoding.

Theorem 3 (Correctness of pebbling SAT encoding).

$\Psi = \Psi_1 \wedge \Psi_2 \wedge \Psi_3 \wedge \Psi_4$ is satisfiable iff there exists a pebbling strategy using no more than k pebbles

Proof. Suppose Ψ is satisfiable and let \mathcal{I} be a satisfying variable assignment interpreted as the set of true variables. We will use $P(x, j, t)$ as an abbreviation for $p_{x,j,(t-1)} \notin \mathcal{I}$ and $p_{x,j,t} \in \mathcal{I}$. Since \mathcal{I} satisfies Ψ_3 , in $P(x, j, t)$ x is uniquely defined by j and t and we can write $P(j, t)$ instead. First we will prove the following assertion. For every $t \in \{1, \dots, n\}$ there exists exactly one $j \in \{1, \dots, n\}$ such that $P(j, t)$. Ψ_1 states that the root v_n has to be pebbled in the last round and Ψ_2 states that no node is pebbled initially. So for n there has to be a $t \in \{1, \dots, n\}$ such that $P(n, t)$. \mathcal{I} satisfies Ψ_4 , therefore for every predecessor of v_j of v_n there exists $x \in \{1, \dots, k\}$ such that $p_{x,j,(t-1)}$. Using the same argument for v_j like for v_n there has to be a $t' \in \{1, \dots, (t-1)\}$ such that $P(j, t')$. Every node of the proof is a recursive ancestor of the root, therefore for every $j \in \{1, \dots, n\}$ there exists at least one $t \in \{1, \dots, n\}$ such that $P(n, t)$. For every $t \in \{1, \dots, n\}$ Ψ_4 ensures that if $P(n, t)$ is true \mathcal{I} then there is no $i \in \{1, \dots, n\}, i \neq j$ such that $P(i, t)$, which proves the assertion. The assertion implies the existence of a bijection $\tau : \{1, \dots, n\} \rightarrow \{v_1, \dots, v_n\}$ such that $\tau(n) = v_n$ and $\tau(t) = j$ iff $P(j, t)$. Therefore $\sigma := \{\tau(1), \dots, \tau(n)\}$ is well defined. σ is a pebbling strategy, because $\tau(n) = v_n$, rule 1 is obeyed because of Ψ_4 , rule 2 is obeyed, because unpebbling moves are given implicit (see Theorem 1) and rule 3 is obeyed because τ is a bijection. Ψ_3 being satisfied ensures that σ uses no more than k pebbles.

Suppose there is a pebbling strategy σ using no more than k pebbles. Let the function $\text{free} : \{1, \dots, n\} \rightarrow 2^{\{1, \dots, k\}} \setminus \emptyset$ be defined recursively as follows and $\text{peb}(t) = \min(\text{free}(t))$.

$$\text{free}(t) = \begin{cases} 1 & : t = 1 \\ \text{free}(t-1) \setminus \{\text{peb}(t-1)\} \cup & : \text{otherwise} \\ \left\{ \begin{array}{l} \text{peb}(s) \mid \sigma_s \in P_{\sigma_{t-1}}^\varphi, s \in \{1, \dots, t-2\} \text{ and for all } v \in C_{\sigma_s}^\varphi \\ \text{there exists } r \in \{1, \dots, t-1\} : \sigma_r = v \end{array} \right\} & \end{cases}$$

Intuitively, $\text{free}(\cdot)$ keeps track of the unused pebbles in each round. If a pebble is placed on a node, it is not free anymore. Pebbles are made free again by the implicit unpebbling moves, which correspond to the second set in the recursive definition of $\text{free}(\cdot)$. Since σ uses no more than k pebbles, $\text{free}(\cdot)$ is well defined.

Let \mathcal{I} be a set of variables of Ψ defined as follows. $p_{x,j,t} \in \mathcal{I}$ iff $t > 0$ and there exists $s \in \{1, \dots, t\}$ such that $\text{peb}(s) = x$, $\sigma_s = v_j$ and for all $r \in \{s+1, \dots, t\}$: $x \notin \text{free}(r)$.

\mathcal{I} is a satisfying assignment for Ψ . Ψ_1 is satisfied, because $\sigma_n = v_n$, therefore trivially $p_{\text{peb}(n),n,n} \in \mathcal{I}$. Clearly Ψ_2 is satisfied by \mathcal{I} as no variables with $t = 0$ are included in \mathcal{I} . To see that Ψ_3 is satisfied, suppose there exist x, t, i, j such that $i \neq j$ and $\{p_{x,j,t}, p_{x,i,t}\} \subseteq \mathcal{I}$. Then by definition of \mathcal{I} there exist unique t_1 and t_2 such that $\text{peb}(t_1) = x$, $\sigma_{t_1} = v_j$ and $\text{peb}(t_2) = x$, $\sigma_{t_2} = v_i$. From $i \neq j$ follows $v_i \neq v_j$, therefore $t_1 \neq t_2$ w.l.o.g. suppose $t_1 > t_2$. From $\text{peb}(t_2) = x$, $p_{x,i,t} \in \mathcal{I}$ and $t \geq t_1 > t_2$ follows $x \notin \text{free}(t_1)$, which is a contradiction to $\text{peb}(t_1) = x$. Let $P(x, j, t)$ be defined as above. Then from $P(x, j, t)$ follows $\text{peb}(t) = x$ and $\sigma_t = v_j$. Rule 1 of the Bounded Pebbling Game ensures that there if $P(x, j, t)$ is true, then there exists a $y \in \{1, \dots, k\} \setminus \{x\}$ such that $p_{y,i,t-1} \in \mathcal{I}$. Suppose $P(x, j, t)$ and $P(y, i, t)$ both hold for some t , $x \neq y$ and $i \neq j$, then $y = \text{peb}(t) = x$ and $v_j = \sigma_t = v_i$ are both contradictions. Therefore also Ψ_4 is satisfied by \mathcal{I} . \square

6 Greedy Pebbling Algorithms

Theorem 2 and the remarks in the end of section 5 indicate that obtaining an optimal topological order either by enumerating topological orders or by encoding the problem as a satisfiability problem is impractical. This section presents two greedy algorithms that aim at finding good though not necessarily optimal topological order. They are both parameterized by some heuristic described in Section 7, but differ in the traversal direction in which the algorithms operate on proofs.

6.1 Top-Down Pebbling

Top-Down Pebbling (Algorithm 1) constructs a topological order of a proof φ by traversing it from its axioms to its root node. This approach closely corresponds to how a human would play the Bounded Pebbling Game. A human would look at the nodes that are available for pebbling in the current round of the game, choose one of them to pebble and remove pebbles if possible. Similarly the algorithm

Fig. 1: Top-Down Pebbling

keeps track of pebbleable nodes in a set N , initialized as A_φ . When a node v is pebbled, it is removed from N and added to the sequence representing the topological order. The children of v that become pebbleable are added to N . When N becomes empty, all nodes have been pebbled once and a topological order has been found.

```

Input: proof  $\varphi$ 
Output: sequence of nodes  $S$  representing a topological order  $\prec$  of  $\varphi$ 
1  $S = ()$ ; // the empty sequence
2  $N = A_\varphi$ ; // initialize pebbleable nodes with Axioms
3 while  $N$  is not empty do
4   choose  $v \in N$  heuristically;
5    $S = S \mathbin{::} (v)$ ; //  $::$  is the concatenation of sequences
6    $N = N \setminus \{v\}$ ;
7   for each  $c \in C_v^\varphi$  do // check whether  $c$  is now pebbleable
8     if  $\forall p \in P_c^\varphi : p \in S$  then
9        $N = N \cup \{c\}$ ;
10    end
11  end
12 end
13 return  $S$ ;

```

Algorithm 1: Top-Down Pebbling

Example 2. Top-Down Pebbling often ends up finding a sub-optimal pebbling strategy regardless of the heuristic used. Consider the graph shown in Figure 1 and suppose that top-down pebbling has already pebbled the initial sequence of nodes $(1, 2, 3)$. For a greedy heuristic that only has information about pebbled nodes, their premises and children, all nodes marked with 4? are considered equally worthy to pebble next. Suppose the node marked with 4 in the middle graph is chosen to be pebbled next. Subsequently, pebbling 5 opens up the possibility to remove a pebble after the next move, which is to pebble 6. After that only the middle subgraph has to be pebbled. No matter in which order this is done, the strategy will use six pebbles at some point. One example sequence

and the point where six pebbles are used are shown in the rightmost picture in Figure 1.

6.2 Bottom-Up Pebbling

Bottom-Up Pebbling (Algorithms 2 and 3) constructs a topological order of a proof φ while traversing it from its root node to its axioms. The algorithm constructs the order by visiting nodes and their premises recursively. At every node v the order in which the premises of v are visited is decided heuristically. After visiting the premises, n is added to the current sequence of nodes. Since axioms do not have any premises, there is no recursive call for axioms and these nodes are simply added to the sequence. The recursion is started by a call to visit the root. Since all proof nodes are ancestors of the root, the recursive calls will eventually visit all nodes once and a topological total order will be found. Bottom-Up Pebbling corresponds to how the apply function $\text{ap}(\cdot)$ was defined in Section 4 with the addition of a visit order of the premises for each node and the omission of calls to previously processed nodes.

<p>Input: proof φ with root node r Output: sequence of nodes S representing a topological order \prec of φ</p> <pre> 1 $S = ()$; // the empty sequence 2 $V = \emptyset$; 3 return $\text{visit}(\varphi, r, V, S)$;</pre>
--

Algorithm 2: Bottom-Up Pebbling

<p>Input: proof φ Input: node v Input: set of visited nodes V Input: initial sequence of nodes S Output: sequence of nodes</p> <pre> 1 $V_1 = V \cup \{v\}$; $N = P_v^\varphi \setminus V$; // Only unprocessed premises are visited 2 $S_1 = S$; 3 while N is not empty do 4 choose $p \in N$ heuristically; $N = N \setminus p$; 5 $S_1 = S_1 \mathbin{:::} \text{visit}(\varphi, p, V, S)$; // $:::$ is the concatenation of sequences 6 end 7 return $S_1 \mathbin{:::} (v)$;</pre>

Algorithm 3: visit

Fig. 2: Bottom-Up Pebbling

Example 3. Figure 2 shows part of an execution of Bottom-Up Pebbling on the same proof as presented in Figure 1. Nodes chosen by the heuristic, to be processed before the respective other premise, are marked dashed. Suppose that similarly to the Top-Down Pebbling scenario, nodes have been chosen in such a way that the initial pebbling sequence is (1, 2, 3). However, the choice of where to go next is predefined by the dashed nodes. Consider the dashed child of node 3. Since 3 has been completely processed, the other premise of its dashed child is visited next. The result is that node the middle subgraph is pebbled while only one external node is pebbled, while it have been two in the Top-Down scenario. At no point more than five pebbles will be used for pebbling the root node, which is shown in the bottom right picture of the figure. This is independently of the heuristic choices.

Not that this example underlines the point of two observations: pebbling choices should be made local and hard subgraphs should be pebbled early.

6.3 Remarks about Top-Down and Bottom-Up Pebbling

In principle every topological order of a given proof can be constructed using Top-down or Bottom-up Pebbling. Both algorithms traverse the proof only once and have linear run-time in the proof length (assuming that the heuristic choice requires constant time). Example 2 shows a situation where Top-Down Pebbling may pebble a node that is far away from the previously pebbled nodes. This results in a sub-optimal pebbling strategy. As discussed in Example 3, Bottom-Up Pebbling is more immune to this non-locality issue, because queuing up the processing of premises enforces local pebbling. This suggests that Bottom-Up is better than Top-Down, which is confirmed by the experiments in Section 8.

7 Heuristics

Heuristics are used in both pebbling algorithms to choose one node out of a set N . For **Top-Down** Pebbling, N is the set of pebbleable nodes, and for **Bottom-Up** Pebbling, N is the set of unprocessed premises of a node. The following definition clarifies what a heuristic in our setting is.

Definition 10 (Heuristic and Basic Heuristics).

Let φ be a proof with nodes V . A basic heuristic h for φ is a set totally ordered set S_h together with a node evaluation function $e_h : V \rightarrow S_h$. A heuristics for φ is finite a sequence $(e_{h_1}, \dots, e_{h_n})$ of basic heuristics such that the node evaluation of e_{h_n} is injective. The choice of the heuristic for a set $N \subseteq V$ is some $v \in N$ such that $v = \operatorname{argmax}_{v \in N} e_{h_1}(v)$ if v is unique and the choice of the heuristic $(e_{h_2}, \dots, e_{h_n})$ for $\{v \in N \mid v = \operatorname{argmax}_{v \in N} e_{h_1}(v)\}$. This process will eventually terminate, because of the limitation to e_{h_n} .

Note that to satisfy the requirement for e_{h_n} , some trivial node evaluation like mapping nodes to their address in memory can be used. In the next chapters we present basic heuristics, which are cheap to compute and are justified by relating them to the semantics of the Bounded Pebbling Game. We will not elaborate on effects of reordering the basic heuristics of heuristics and will therefore omit the basic.

7.1 Number of Children Heuristic (“Ch”)

The **Number of Children** heuristic uses the number of children of a node v as evaluation function, i.e. $e_h(v) = |C_v^\varphi|$ and $S_h = \mathbb{N}$. The intuitive motivation for this heuristic is that nodes with many children will require many pebbles, and subproofs containing nodes with many children will tend to be more spacious. Example 4 shows why it is a good idea to process spacious subproofs first.

Example 4. Figure 3 shows a simple proof φ with two subproofs φ_1 (left branch) and φ_2 (right branch). As shown in the leftmost diagram, assume $s(\varphi_1, \prec_1) = 4$ and $s(\varphi_2, \prec_2) = 5$, where \prec_1 and \prec_2 represent some topological order of the respective subproofs. After pebbling one of the subproofs, the pebble on its root node has to be kept there until the root of the other subproof is also pebbled. Only then the root node can be pebbled. Therefore, $s(\varphi, \prec) = s(\varphi_j, \prec_j) + 1$ where $\prec = (\text{root}) \prec \dots \prec_i \prec \dots \prec_j$ and i, j are the indexes of the subproofs pebbled first and second respectively. Choosing to pebble the less spacious subproof φ_1 first results in $s(\varphi, \prec) = 6$, while pebbling the more spacious one first gives $s(\varphi, \prec) = 5$.

Note that this example shows a simplified situation. The two subproofs do not share nodes. Pebbling one of them does not influence the pebbling number of the other.

Fig. 3: Spacious subproof first

7.2 Last Child Heuristic (“*Lc*”)

As discussed in Section 4 in the proof of Theorem 1, the best moment to unpebble a node v is as soon as its last child w.r.t. a topological order \prec is pebbled. This insight is used for the **Last Child** heuristic that chooses nodes that are last children of other nodes. Pebbling a node that allows another one to be unpebbled is always a good move. The current number of used pebbles (after pebbling the node and unpebbling one of its premises) does not increase. It might even decrease, if more than one premise can be unpebbled. For determining the number of premises of which a node is the last child, the proof has to be traversed once, using some topological order \prec . Before the traversal, $e_h(v)$ is set to 0 for every node v . During the traversal $e_h(v)$ is increased by 1, if v is the last child of the currently processed node w.r.t. \prec . For this heuristic $S_h = \mathbb{N}$. To some extent, this heuristic is paradoxical: v may be the last child of a node v' according to \prec , but pebbling it early may result in another topological order \prec^* according to which v is not the last child of v' . Nevertheless, sometimes the proof structure ensures that some nodes are the last child of another node irrespective of the topological order. An example is shown in Figure 4, where the dashed line denotes a recursive predecessor relationship and the bottommost node is the last child of the top right node in every topological order.

Fig. 4: Bottommost node as necessary last child of right topmost node

7.3 Node Distance Heuristic (“*Dist(r)*”)

In Example 2 and Section 6.3 it has been noted that **Top-Down** Pebbling may perform badly if nodes that are far apart are selected by the heuristic. The **Node Distance** heuristic prefers to pebble nodes that are close to pebbled nodes. It does this by calculating spheres with a radius up to the parameter r around

nodes. A sphere $K_r^G(v)$ with radius r around the node v in the graph $G = (V, E)$ is the set $\{p \in V \mid v \text{ can be reached from } p \text{ visiting at most } r \text{ edges}\}$, where edges are considered undirected. The heuristic uses the following functions based on the spheres:

$$\begin{aligned} d(v) &:= \begin{cases} -\min(D) \text{ such that } D = \{r \mid K_r^G(v) \text{ contains a pebbled node}\} \neq \emptyset \\ \infty \text{ otherwise} \end{cases} \\ s(v) &:= |K_{-d(v)}^G(v)| \\ l(v) &:= \max_{\prec} K_{-d(v)}^G(v) \\ e_h(v) &:= (d(v), s(v), l(v)) \end{aligned}$$

where \prec denotes the order of previously pebbled nodes. So $S_h = \mathbb{Z} \times \mathbb{N} \times P$ together with the lexicographic order using, respectively, the natural smaller relation $<$ on \mathbb{Z} and \mathbb{N} and \prec on N . The spheres $K_r(v)$ can grow exponentially in r . Therefore the maximum radius has to be kept small.

7.4 Decay Heuristics (“ $Dc(h_u, \gamma, d, com)$ ”)

Decay heuristics denote a family of meta heuristics. The idea is to not only use the evaluation of a single node, but also to include the evaluations of its premises. Such a heuristic has four parameters: an underlying heuristic h_u defined by an evaluation function e_u together with a well ordered set S_u , a decay factor $\gamma \in \mathbb{R}^+ \cup \{0\}$, a recursion depth $d \in \mathbb{N}$ and a combining function $com : S_u^n \rightarrow S_u$ for $n \in \mathbb{N}$.

The resulting heuristic node evaluation function e_h is defined with the help of the recursive function rec :

$$\begin{aligned} rec(v, 0) &:= e_u(v) \\ rec(v, k) &:= e_u(v) + com(rec(p_1, k-1), \dots, rec(p_n, k-1)) * \gamma \\ &\quad \text{where } P_v^\varphi = \{p_1, \dots, p_n\} \\ e_h(v) &:= rec(v, d) \end{aligned}$$

8 Experiments

All the pebbling algorithms and heuristics described in the previous sections have been implemented in the hybrid functional and object-oriented programming language Scala (www.scala-lang.org) as part of the **Skeptik** library for proof compression (github.com/Paradoxika/Skeptik) [17].

To evaluate the algorithms and heuristics, experiments were executed¹ on four disjoint sets of proof benchmarks (Table 1). **TraceCheck₁** and **TraceCheck₂** contain proofs produced by the SAT-solver **PicoSAT** [?] on unsatisfiable benchmarks from the SATLIB (www.satlib.org/benchm.html) library. The proofs² are

¹ The Vienna Scientific Cluster VSC-2 (<http://vsc.ac.at/>) was used.

Name	Number of proofs	Maximum length	Average length
TraceCheck ₁	2239	90756	5423
TraceCheck ₂	215	1768249	268863
veriT ₁	4187	2241042	103162
veriT ₂	914	120075	5391

Table 1: Proof benchmark sets

in the TraceCheck proof format, which is one of the three formats accepted at the *Certified Unsat* track of the SAT-Competition. veriT₁ and veriT₂ contain proofs produced by the SMT-solver veriT (www.verit-solver.org) on unsatisfiable problems from the SMT-Lib (www.smtlib.org). These proofs³ are in a proof format that resembles SMT-Lib’s problem format and they were translated into pure resolution proofs by considering every non-resolution inference as an axiom.

Table 2 summarizes the results of the experiments. The two presented order finding algorithms are tested in combination with the four presented heuristics. The Children and LastChild heuristics were tested on all four benchmark sets. The Distance and Decay heuristics were tested on the sets TraceCheck₂ and veriT₂. The relative performance is calculated according to Formula 1, where f is an algorithm with a heuristic, P is the set of proofs the heuristic was tested on and G are all combinations of algorithms and heuristic that were tested on P . The time used to construct orders is measured in processed nodes per millisecond. Both columns show the best and worst result in boldface.

$$\text{relative_performance}(f, P, G) = \frac{1}{|P|} * \sum_{\varphi \in P} \left(1 - \frac{s(\varphi, f(\varphi))}{\text{avg}_{g \in G} s(\varphi, g(\varphi))} \right) \quad (1)$$

Table 2 shows that the Bottom-Up algorithm constructs topological orders with much smaller space measures than the Top-Down algorithm. This fact is visualized in Figure 5, where each dot represents a proof φ and the x and y coordinates show the space of φ with the topological orders found by, respectively, the best Top-Down and Bottom-Up algorithms for φ . The LastChild heuristic produces the best results and the Children heuristic also performs well. The Distance heuristic produces the worst results, which could be due to the fact that the radius is too small for big proofs with thousands of proof nodes. The Decay heuristics unfortunately do not show an improvement of the underlying heuristic.

Some additional heuristics, not described in this work, designed specifically for Top-Down Pebbling were tested on small benchmark sets. These heuristics

Table 2: Experimental results

aimed at doing local pebbling without having to calculate full spheres. For example pebbling nodes that allow other nodes to be unpebbled in the next move can be preferred. Unfortunately, none of the additional heuristics showed promising results.

The Bottom-Up algorithm does not only produce better results, it is also much faster, as can be seen in the last column of Table 2. The reason probably is the number of comparisons that the algorithms make. For Bottom-Up the set N of possible choices consists of the premises of a single node only, and usually $|N| \in O(1)$ (e.g. for a binary resolution proof, $N \leq 2$ always). For Top-Down the set N is the set of currently pebbleable nodes, which can be large (e.g. for a perfect binary tree with $2n - 1$ nodes, initially $|N| = n$). Possibly for some heuristics, Top-Down algorithms could be made more efficient by using, instead of a set, an ordered sequence of pebbleable nodes together with their memorized heuristic evaluations.

Unsurprisingly the radius used for the Distance Heuristic has a severe impact on the speed, which decreases rapidly as the maximum radius increases. With radius 5, only a few small proofs were processed in a reasonable amount of time.

Fig. 5: Spaces obtained with best Bottom-Up and Top-Down heuristics

Figure 6 relates for each proof the smallest space measure obtained by all algorithms tested on the respective proof and its length in number of nodes. Note that the y-axis, showing the space measures, scale is lower by a factor of 100 compared to the scale of the x-axis, which displays the proof lengths. On average the smallest space measure of a proof is 44,1 times smaller than its length. This shows the impact that the usage of deletion information together with well constructed topological orders can have. When these techniques are used, on average 44,1 times less memory is required for storing nodes in memory while proof processing.

Several algorithms for compressing proofs with respect to space have been conceived. The experimental evaluation clearly shows that the so-called Bottom-Up algorithms are faster and compress more than the more natural, straightforward and simple Top-Down algorithms. Both kinds of algorithms are parameterized by a heuristic function for selecting nodes. The best performances are achieved with the simplest heuristics (i.e. Last Child and Number of Children). More sophisticated heuristics provided little extra compression but cost a high price in execution time. Future work could investigate heuristics that take advantage of the particular shape of proofs generated by analysis of conflict graphs.

Acknowledgments: We would like to thank Armin Biere for clarifying why resolution chains are not left-associative in the TraceCheck proof format.
